Foot disease affects nearly 6% of people with diabetes¹ and includes infection, ulceration, or destruction of tissues of the foot.² It can impair patients' quality of life and affect social participation and livelihood.³ Between 0.03% and 1.5% of patients with diabetic foot require an amputation.⁴ Most ulcers can be prevented with good foot care and screening for risk factors for a foot at risk of complications.⁵ We provide an update on the prevention and initial management of diabetic foot in primary care.

What causes diabetic foot?

Uncontrolled diabetes contributes to the development of neuropathy and peripheral arterial disease by complex metabolic pathways.⁶ Loss of sensation caused by peripheral neuropathy, ischaemia due to peripheral arterial disease, or a combination of these may lead to foot ulcers. A systematic review (78 studies from 84 cohorts) reports a prevalence of 0.003-2.8% for diabetes related peripheral neuropathy and 0.01-0.4% for diabetes related peripheral arterial disease.⁴ Figure 1 depicts factors that contribute to foot complications.

Diabetes is also implicated in Charcot arthropathy, which involves progressive destruction of the bones, joints, and soft tissues, most commonly in the ankle and foot. Diabetes related Charcot's arthropathy has a reported prevalence between 0.08% and 13%, but there are no high quality epidemiological studies on Charcot's foot.^{7,8} A combination of neuropathy, abnormal loading of foot, repeated micro trauma, and metabolic abnormalities of bone leads to inflammation, causing osteolysis, fractures, dislocation, and deformities.⁹

WHAT YOU NEED TO KNOW

- Diabetic foot can be prevented with good glycaemic control, regular foot assessment, appropriate footwear, patient education, and early referral for pre-ulcerative lesions
- Examine the feet of people with diabetes for any lesions and screen for peripheral neuropathy and peripheral arterial disease, which can lead to injuries or ulceration
- Refer patients with foot ulceration and signs of infection, sepsis, or ischaemia immediately to a specialised diabetic foot centre for surgical care, revascularisation, and rehabilitation

Sources and selection criteria

This clinical update is based on recommendations in the standard treatment guideline, The diabetic foot: prevention and management in India 2016, published by the Indian Ministry of Health and Family Welfare.^{3,3} A multidisciplinary guideline development group consisting of surgeons, primary care practitioners, and a patient representative developed these guidelines, with inputs from experts in diabetes, diabetic foot rehabilitation, and vascular surgery. The group included representation from rural and urban India, and public and private sectors.

The guideline development group selected recommendations from the National Institute for Health and Care Excellence clinical guideline 19. Diabetic foot problems: prevention and management. Updated 2016, International Working Group on the Diabetic Foot guidance on the prevention of foot ulcers in at-risk patients with diabetes 2015, National Institute for Health and Care Excellence. Peripheral arterial disease: diagnosis and management. Guideline 147, 2012, and Infectious Diseases Society of America clinical practice guideline for the diagnosis and treatment of diabetic foot infections, 2012.^{9,10,21,32} Some recommendations were adopted unchanged, whereas others were adapted taking into account the challenges of a low resource setting, such as availability of public and private health infrastructure, equipment, staffing, and current capacity at different levels of care.

In low and middle income countries barefoot walking, lack of awareness, delay in seeking care, and shortage of trained healthcare providers and foot care services are common factors that add to the burden of foot disease.

How is it diagnosed?

A thorough foot examination is important to detect the disease early. Screening for peripheral neuropathy and peripheral arterial disease can help identify patients at risk of foot ulcers. A history of ulcers or amputations and poor glycaemic control increase the risk.

Assess the patient's general condition for signs of toxicity or sepsis such as feeling unwell, looking sick, showing abnormal behaviour, circulation, or respiration, with or without fever. Examine the feet at each follow-up visit for active disease such as ulceration or gangrene

HOW PATIENTS WERE INVOLVED IN THE CREATION OF THIS ARTICLE

No patients were involved in the creation of this article.

P

Fig 1 | Risk factors and mechanism for foot ulcer and amputation

(fig 2). Look for lesions such as fungal infection, cracks and skin fissures, deformed nails, macerated web spaces, calluses, and deformities such as hammer toes, claw toes, and pes cavus, which increase the risk of ulceration (fig 3). Feel the temperature of the feet with the dorsum of your hand. A cold foot might suggest ischaemia, and increased warmth with redness and swelling might suggest inflammation such as acute Charcot foot or cellulitis.

Peripheral neuropathy

The aim of screening is to identify patients with loss of protective sensation in the feet. Most guidelines recommend the 10 g monofilament for neuropathy assessment (fig 4) in people with diabetes.⁹⁻¹⁰ This monofilament exerts a 10 g buckling force when it bends. An inability to sense a 10 g pressure is the current consensus definition of loss of protective sensation. The test is portable, cheap, and easy to perform (box 1).¹² Despite the widespread use of the monofilament test, its accuracy in diagnosing neuropathy is variable.¹⁶ The test may be combined with another test to screen for neuropathy, such as a biothesiometer or a graduated tuning fork (Rydel Seiffer) to assess vibration perception threshold.¹⁷⁻¹⁸

Peripheral arterial disease

Ask for a history of intermittent claudication and rest

Fig 2 | Gangrene and ulcer in foot at high risk (previous toe amputation)

pain, which suggest peripheral arterial disease.¹⁹ Palpate the posterior tibial artery and dorsalis pedis artery in both feet and record pulsations as absent or present.²⁰

The ankle brachial index is an adjunct measure to diagnose peripheral arterial disease.¹⁹⁻²¹ It is the ratio of the highest systolic blood pressure at the ankle (dorsalis pedis artery or posterior tibial artery) to the systolic blood pressure at the arm, and is measured using a Doppler device.¹⁰ See box 2 on grading the severity of obstruction. Measurement of the ankle brachial index is user dependent. People with diabetes can often have falsely raised ankle brachial index levels as a result of poor compressibility from calcified arteries.²¹ Furthermore, availability of equipment, time constraints, and lack of training are reported as major barriers to ankle brachial index testing in primary care.²³⁻²⁵

On the basis of this initial assessment, patients can be categorised as having a low, moderate, or high risk of diabetic foot (see fig 5).⁹

Fig 3 | Hammer toe deformity with callus and ulcer. Hammer toe is caused by weakened muscles in the foot. The joint connecting the foot with the toe bends upwards and the joint in middle of the toe bends downwards towards the floor. This results in the toe curling under the foot and being subjected to excessive ground reaction forces during walking.

Fig 4 | Monofilament test: testing sites and application. The nine plantar sites are the distal great toe; third toe; fifth toe; first, third, and fifth metatarsal heads; medial foot, lateral foot, and heel; and one dorsal site

How can it be prevented?

Regular foot examination

The suggested frequency for follow-up is based on expert consensus (fig 5). For people at low risk, continue annual foot assessments as they could progress to moderate or high risk. Emphasise the importance of foot care and monitoring glycaemic control.

More frequent follow-up is advised in patients at moderate or high risk, such as those with a foot deformity or with a diagnosis of peripheral neuropathy or peripheral arterial disease at initial assessment. Repeat testing for neuropathy is not necessary if diagnosed previously. Neuropathy reversal is not established in studies. A quick inspection for a breach in skin integrity or ulceration should suffice. Patients with asymptomatic peripheral arterial disease may be followed up in primary care and managed as in guidelines for peripheral arterial disease.²¹

Refer patients with calluses and deformed toe nails to preventive podiatry services for basic nail and skin care, including debridement of calluses. Timely referral to foot protection services for control of risk factors in patients with diabetes prevents infection, gangrene, amputation, or

Box 2: Ankle brachial index

The severity of peripheral arterial disease is interpreted²²:

- 0.91-1.3—Normal
- 0.70-0.90—Mild obstruction
- 0.40-0.69—Moderate obstruction
- <0.40—Severe obstruction
- >1.3—Poorly compressible vessel

death, and reduces hospital admissions and costs.⁹

Glycaemic control

Early and good glycaemic control is effective in preventing neuropathy but there is a lack of studies to show that glycaemic control reverses neuropathy.²⁶ Discuss optimal blood sugar and glycated haemoglobin (HbA_{1c}) targets with patients and monitor these as per standard guidelines for diabetes care to prevent or slow the progression of peripheral neuropathy.^{27 28}

Patient education

Offer people with diabetes or their caregivers, or both, oral and written information on:

- The importance of blood glucose control and modifiable cardiovascular risk factors such as diet, exercise, body weight, and cessation of smoking.
- The importance of foot care and advice on basic foot care (see box 3). While offering advice consider the patient's cultural practices and religious beliefs as well as social and family support.
- The person's current risk of developing a foot problem.
- When to seek professional help and who to contact in foot emergencies.

Evidence for the effectiveness of patient education on foot care is lacking. A Cochrane review of 11 randomised controlled trials concluded that brief foot care education alone does positively influence patient knowledge and behaviour in the short term, but it is ineffective in preventing diabetic foot ulcers. Education in a structured, organised, and repetitive manner, combined with preventive interventions may, however, prevent foot problems.²⁹ Although the International Working Group on the Diabetic Foot acknowledges the limited evidence on long term efficacy of patient education, it recommends some form of patient education to improve their foot care knowledge and behaviour.¹⁰

Footwear

Occlusive footwear causes sweating and can predispose to fungal infection,^{30 31} particularly in tropical countries. Ideally, footwear for people with diabetes should have a wide toe box, soft cushioned soles, extra depth to accommodate orthoses if required, and laces or Velcro for fitting and adjustments. A new pair of shoes can be worn for a short while daily until comfortable. Patient compliance to prescribed footwear is usually poor, particularly at home where they are more active.²⁹ Patients with plantar ulcers at forefoot or heel may be offered offloading footwear (fig 6) to allow ulcer healing and prevent recurrence.

When to refer?

Refer immediately patients with a life threatening or limb threatening problem such as foot ulceration with fever

Box 1: Monofilament test (fig 4)

Procedure—Ask the patient to sit or lie down with both legs stretched out and soles exposed. Explain the procedure and make him or her familiar with the sensation by applying the monofilament on a sensitive area such as the palm. Ask the patient to close his or her eyes and to say “yes” every time touch is felt on the soles, no matter how lightly it is perceived. Place the monofilament at 90° to the skin and press it till it buckles to 1 cm, then hold there for 1-2 seconds and remove.¹¹ Test different sites in a random sequence with a pause (sham application) to prevent the patient from guessing the next application. If the patient fails to respond at a site, revisit the same site two more times in a random sequence during the assessment. If the patient does not perceive the sensation all the three times, then record the result as loss of protective sensation.¹¹ Loss of protective sensation even at a single site puts the patient at risk for foot complications.

Test sites and threshold—Most studies recommend testing at 10 sites.

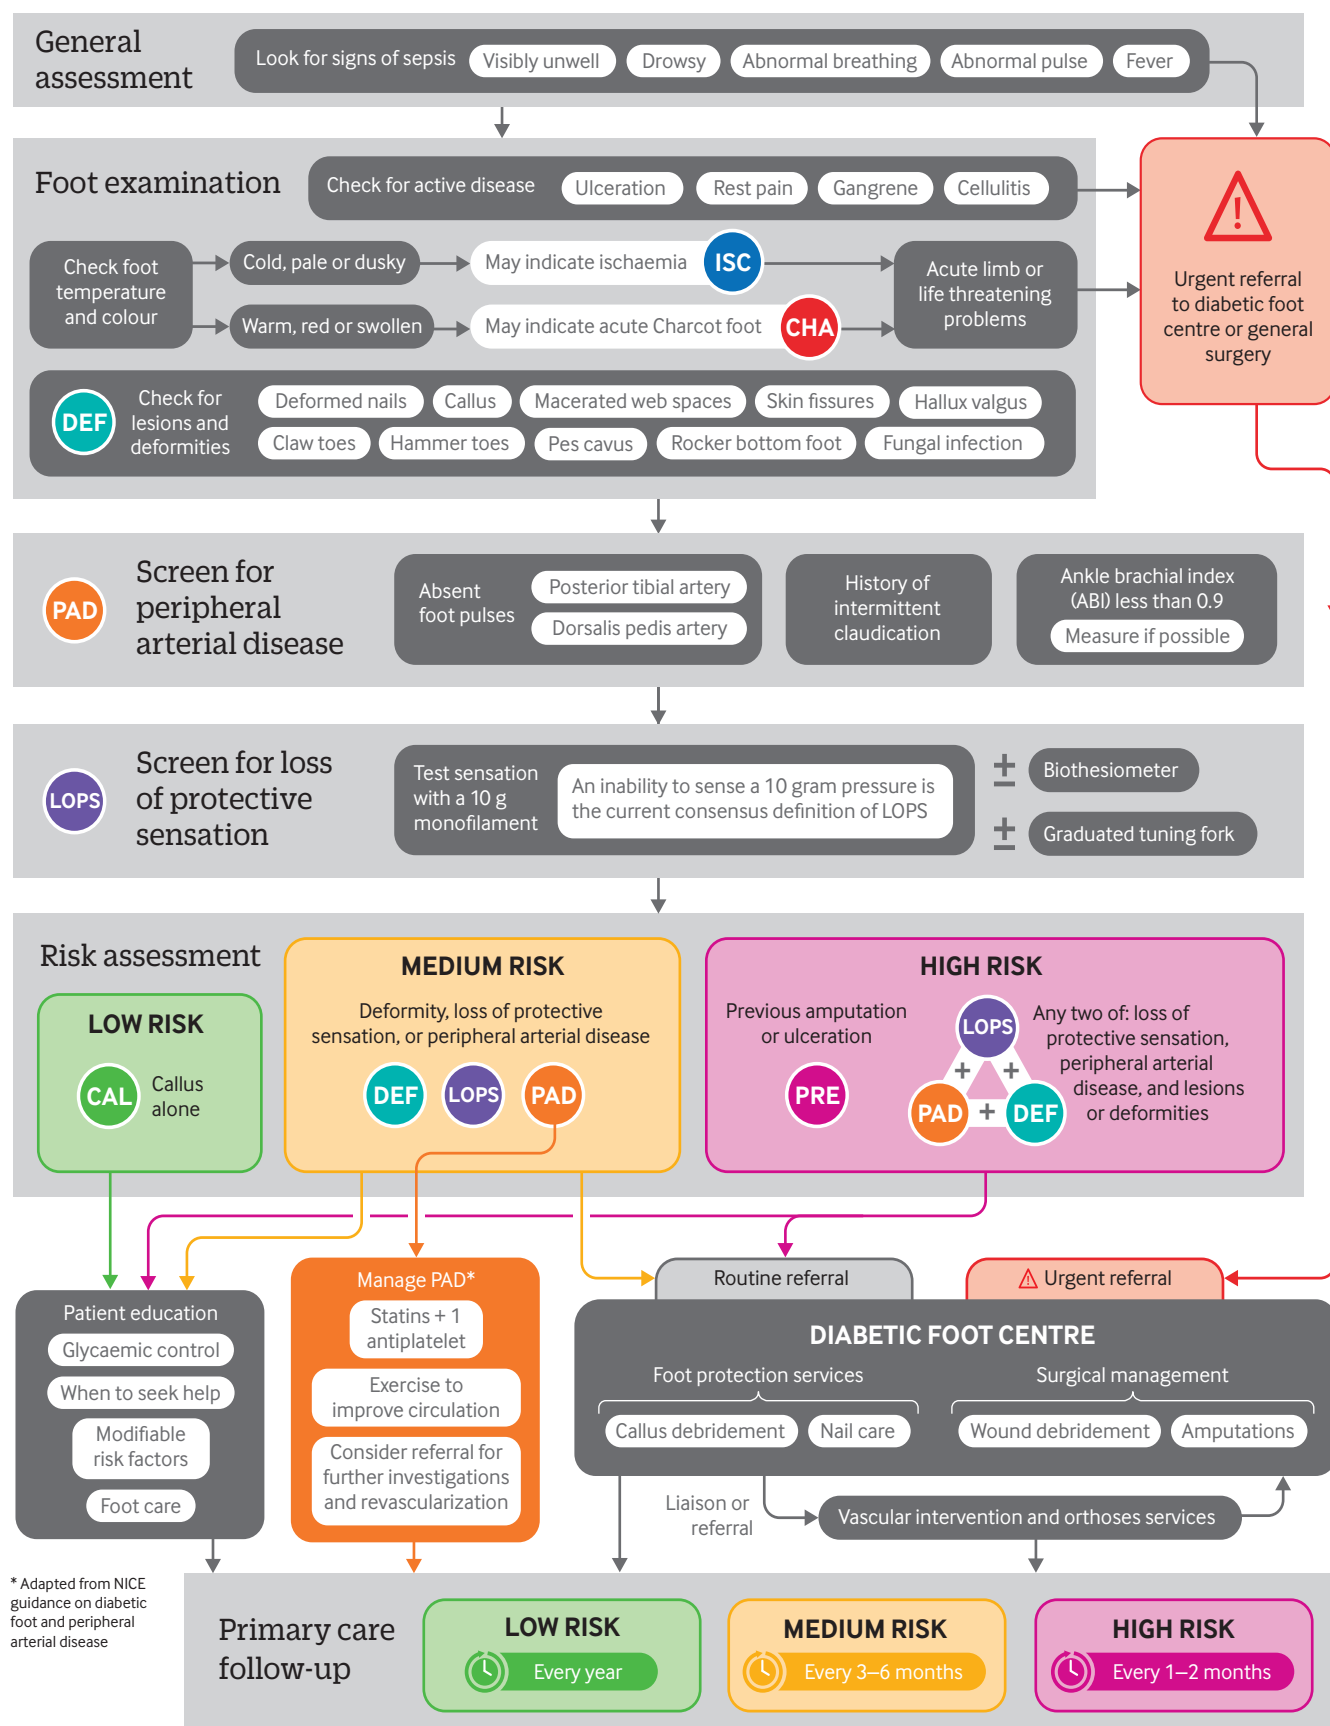

Inability to perceive a 10 g monofilament three times at even a single site means the patient has loss of protective sensation.^{11 12}

Inter-observer variability—This is reported to be more on the heels, with a higher chance of a false positive result.¹³ Exercise caution before labelling a heel as insensate, especially if screening a population where barefoot walking is common.

Durability of monofilaments—Monofilaments tend to fatigue with repeated use, and a 24 hour recovery period is recommended after 100 compression cycles.¹⁴ Replace a monofilament after three months of regular use.

Fig 5 | Assessment of risk of diabetic foot

Box 3: Tips on foot care for people with diabetes¹⁹

- Inspect both feet daily, including the area between the toes. Ask a caregiver to do this if you are unable to.
- Wash the feet daily with water at room temperature, with careful drying, especially between the toes.
- Use lubricating oils or creams for dry skin, but not between the toes.
- Cut nails straight across.
- Do not remove corns and calluses using a chemical agent or plaster. They should not be excised at home and must be managed by trained staff.
- Always wear socks with shoes and check inside shoes for foreign objects before wearing them.
- Avoid walking barefoot at all times.
- Ensure a qualified healthcare provider examines your feet regularly.
- Notify the healthcare provider at once if a blister, cut, scratch, or sore develops.

or any signs of sepsis; ulceration with limb ischaemia; gangrene, or a suspected deep seated soft tissue or bone infection usually indicated by either a grossly swollen foot with shiny skin and patches of discoloration or a gritty feel to the bone during a probe to bone test in an open wound.⁹ Refer to a specialised diabetic foot centre or to general surgery for wound care, revascularisation if needed, offloading, and rehabilitation.

Explain to patients the need to seek specialist care to limit complications. Provide detailed and clear communication before patients are referred so that

How can diabetic foot care services be organised in India?

Nearly 415 million people globally have diabetes, with 75% living in low and middle income countries. In India about 70 million people have diabetes, and the number is projected to rise to 125 million by 2040.³⁴

The National Institute for Health and Care Excellence guideline on diabetic foot recommends a three tier system for foot care: primary healthcare for preventive services and appropriate referral of diabetic foot; foot protection services at community level for podiatric care and management of simple foot problems; and multidisciplinary foot care services at tertiary level to handle complex foot problems.⁹

In low and middle income countries, primary care doctors are not trained in diabetic foot care, podiatry as a discipline is emerging, and multidisciplinary foot care services are available at few tertiary care centres.

We recommend training primary care doctors in diabetic foot care, particularly in countries with a high burden of diabetes. Referral hospitals should develop diabetic foot centres under the specialty of general surgery. These centres would provide foot protection services such as callus debridement and nail care, and surgeries such as wound debridement and minor or major amputations. Multidisciplinary foot care services should be provided at all tertiary level hospitals with facilities for vascular intervention and orthoses.

multidisciplinary care can be facilitated at the earliest opportunity.

Before referral, wash the ulcer with clean water or saline and apply a sterile inert dressing such as a saline soaked gauze to control exudates and maintain a warm, moist environment for healing. Avoid microbicidal agents such as hydrogen peroxide, povidone iodine, or chlorhexidine to clean or dress the ulcer as these are cytotoxic. Costly antimicrobial dressings are not recommended.⁹ Adjust dressings, footwear, and ambulation to avoid weight bearing on an ulcerated foot.³² Early and aggressive treatment to control infection is important, especially in the presence of an ulcer. Start antibiotic treatment according to antibiotic policy based on local resistance patterns. Before starting antibiotics, take a piece of soft tissue from the base of the ulcer for culture and sensitivity, or take a deep swab for culture.⁹ Refer urgently, within one or two days, patients with a history of rest pain, uncomplicated ulcer, or acute Charcot foot.⁹ For patients with rest pain or intermittent claudication, offer referral to vascular intervention services for further investigations such as Duplex ultrasonography, and consideration for revascularisation.²¹

The management and referral pathways between primary care, specialty diabetic foot centres, and multidisciplinary foot care services need to be integrated (see fig 5).

EDUCATION INTO PRACTICE

- In your practice, what proportion of people with diabetes have had a foot evaluation in the past 12 months?
- Describe how you would screen patients with diabetes for peripheral neuropathy and peripheral arterial disease.
- How would you advise a patient with diabetes about foot care?

Fig 6 | Offloading footwear reduces pressure on a specific part of the foot to allow an ulcer on that part to heal or to prevent new ulcers. The top figure shows footwear that reduced pressure on the forefoot and the footwear shown underneath allows pressure on the heel to be offloaded

SUGGESTIONS FOR FUTURE RESEARCH

- Does grading the severity of peripheral arterial disease using the ankle brachial index help guide interventions to prevent foot ulcers in people with diabetes?
- What is the sensitivity of the monofilament test to diagnose peripheral neuropathy, and the interobserver variation among trained providers?
- What model of patient education is effective in preventing diabetic foot complications?

Contributors: SM, KC, and AM conceived and designed the review. SM and KC created the first draft. AM and AK revised the content and approved the final version to be published. All authors act as guarantors.

Funding: The Indian Ministry of Health and Family Welfare funded the process for development of the standard treatment guideline on Diabetic Foot. The Department for International Development funded the technical assistance provided by Global Health and Development Group (formerly NICE International) to the Guideline Development Group on diabetic foot.

Competing interests: We have read and understood BMJ policy on declaration of interests and declare the following: SM, KC, and AK were members of the guideline development group for the standard treatment guideline on the diabetic foot: prevention and management in India, 2016 published by the Ministry of Health and Family Welfare, government of India. AM provided technical input on methodology to this guideline development group.

Provenance and peer review: This article is one of a series commissioned by the BMJ from the Global Health and Development Group at Imperial College London (formerly NICE International) as part of the International Decision Support Initiative (www.idshealth.org). The BMJ retained full editorial control over external peer review, editing, and publication. Open access fees are funded by the Bill and Melinda Gates Foundation.
